$\qquad$ Pd: $\qquad$ NOTES

## Chemistry Notes: Compounds and Mixtures

| What is a Pure Substance? | - A pure substance is a type of $\qquad$ that includes both $\qquad$ and $\qquad$ <br> - Pure substances cannot be separated by $\qquad$ means such as <br> - Distillation: $\qquad$ a liquid until it evaporates (changes to a $\qquad$ ), then condensing it back to a $\qquad$ -different substances boil at different $\qquad$ , so we can separate different substances this way. <br> - Filtration: the process of removing $\qquad$ from liquids (or gases) <br> - Chromatography: a way to separate different substances based on how $\qquad$ each substance moves through a filter. |
| :---: | :---: |
| What are Elements? | - We have already studied elements: An element is made of $\qquad$ kind of _________-_ <br> - Found on the $\qquad$ |
| What is a Compound? | - A compound is a pure substance that is created by $\qquad$ or more elements joining together. Ex: NaCl , $\qquad$ $\mathrm{CO}_{2}$, $\qquad$ , $\mathrm{NaHCO}_{3}$, and $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$ <br> - Notice that elements combine in many $\qquad$ to make compounds <br> - Ex: $\mathrm{H}_{2} \mathrm{O}$ and $\qquad$ CO and $\qquad$ <br> - Compounds have different $\qquad$ from the elements that they are made of. <br> - Just like letters combine to form $\qquad$ elements combine to form <br> - Most substances are $\qquad$ not pure $\qquad$ <br> - Atoms are held together by $\qquad$ <br> - Chemical bond: the " $\qquad$ " that holds atoms together; involves |
| Atoms combine in predictable numbers | - Chemical $\qquad$ element $\qquad$ in a ratio to represent a $\qquad$ <br> - $\mathrm{CO}_{2} \rightarrow 1$ carbon atom ratio $=1: 2$ <br> 2 oxygen atoms <br> - $\mathrm{H}_{2} \mathrm{O} \rightarrow$ ___ hydrogen atoms ratio $=$ $\qquad$ <br> 1 oxygen atom <br> - Ex. $\mathrm{C}_{2} \mathrm{H}_{4} \mathrm{O} \rightarrow$ $\qquad$ carbon atoms $\qquad$ hydrogen atoms $\qquad$ oxygen atoms <br> - NOTE: we never use the $\qquad$ (the number to the $\qquad$ and slightly $\qquad$ the element symbol) $\qquad$ We simply write the element's symbol to show that there is $\qquad$ of that element in the compound. |
| Practice <br> Writing Compounds | 1. 2 Hydrogen and 1 Oxygen $\qquad$ <br> 2. 4 Carbon 16 Oxygen $\qquad$ <br> 3. 6 Carbon 12 Hydrogen 6 Oxygen $\qquad$ |
| Why do Compounds Form? | - Compounds form to allow elements to become more $\qquad$ <br> - $\qquad$ is flammable when it comes in contact with $\mathrm{H}_{2} \mathrm{O}$, and $\mathrm{Cl}_{2}$ is a $\qquad$ <br> - $\qquad$ is a very stable compound that is neither flammable nor toxic <br> - Compounds that are too $\qquad$ will break down to form the more stable elements |

| How do <br> Compounds <br> Form? | - Compounds form by the interaction between the nuclei and $\qquad$ of 2 or more elements <br> - THE OCTET RULE: an element is most $\qquad$ (happy :D) with $\qquad$ valence electrons <br> - Elements will join $\qquad$ to get $\qquad$ valence electrons <br> - Ex: $\mathrm{CO}_{2}$ : oxygen has $\qquad$ valence electrons and carbon has $\qquad$ If the carbon shares $\qquad$ with $\qquad$ oxygen, everyone will have 8 valence electrons! |
| :---: | :---: |
| Common Compounds you NEED TO KNOW: | - Compounds are used in your $\qquad$ <br> - $\mathrm{H}_{2} \mathrm{O}$ is $\qquad$ <br> - <br> is Carbon Dioxide <br> - $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$ is $\qquad$ , and $\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}$ is $\qquad$ (both are $\qquad$ !) <br> - <br> is table salt <br> - NaClO is $\qquad$ <br> - HCl is hydrochloric acid <br> - ______ is ammonia <br> - $\mathrm{NaHCO}_{3}$ is baking soda <br> - $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ is vinegar <br> - $\mathrm{O}_{2}$ is $\qquad$ |
| What Is A Mixture? | - A mixture is the $\qquad$ combination of $\qquad$ or more substances <br> - It is important to understand that a mixture is $\qquad$ combined <br> - Mixtures can be separated by $\qquad$ means such as filtration, distillation, and chromatography <br> - Mixtures can be divided into $\qquad$ groups: <br> - $\qquad$ mixtures <br> - Heterogeneous mixtures |
| How do Mixtures Form? | - Mixtures form by $\qquad$ putting $\qquad$ or more substances together $\qquad$ , cake batter, etc.). Remember: |
| What Is a Homogeneous Mixture? | - A homogeneous mixture is a mixture that's parts are $\qquad$ distributed <br> - Homogeneous mixtures are commonly called $\qquad$ <br> - Solution $=$ $\qquad$ $+$ $\qquad$ <br> - Solute: substance ("stuff") $\qquad$ <br> - Solvent: substance ("stuff") $\qquad$ <br> - The solvent is present in $\qquad$ quantity <br> - The solute is present in the $\qquad$ quantity <br> - Ex: Salt water: $\qquad$ =solute, $\qquad$ =solvent $\qquad$ is dissolved in solvent (example: saltwater = salt dissolved in water) |
| What Is a Heterogeneous Mixture? | - A heterogeneous mixture is a mixture that is $\qquad$ distributed. <br> - Examples: <br> - Iced tea: The $\qquad$ is floating at the top and therefore is not evenly distributed <br> - Chex Mix: You may find a $\qquad$ number of pretzels or Chex cereal in each handful; therefore, the mixture is $\qquad$ distributed |

| Properties change in solutions | - A solute changes the $\qquad$ properties of a solvent <br> - $\qquad$ point <br> - Solvent (water) $=32^{\circ} \mathrm{F}$ or ____ ${ }^{\circ} \mathrm{C}$ <br> - Solution (sugar water) $=15^{\circ} \mathrm{F}$ or $\qquad$ ${ }^{\circ} \mathrm{C}$ <br> - *the freezing point of a solution is $\qquad$ than the freezing point of the pure solvent* <br> - Example: why do we put salt on a road before it snows? <br> - Boiling point <br> - Solvent (water) $=212^{\circ} \mathrm{F}$ or $\qquad$ ${ }^{\circ} \mathrm{C}$ <br> - Solution (sugar water) $=225^{\circ} \mathrm{F}$ or $\qquad$ ${ }^{\circ} \mathrm{C}$ <br> - *The boiling point of a solution is $\qquad$ than the boiling point of the pure solvent* |
| :---: | :---: |
| The amount of solute that dissolves can vary. | - Concentration: the amount of solute $\qquad$ in the solution at a certain <br> - $\uparrow$ (to $\qquad$ ) concentration = add more $\qquad$ <br> $-\quad \downarrow$ (to $\qquad$ ) concentration = add more $\qquad$ <br> - Dilute: $\qquad$ solute is $\qquad$ in solvent <br> - Concentrated: $\qquad$ solute is $\qquad$ in solvent <br> - Saturated solution: has as much $\qquad$ as it can $\qquad$ at a certain any more solute |
| What is Solubility? | - Solubility: the amount of $\qquad$ that will $\qquad$ in a certain amount of a certain $\qquad$ at a certain $\qquad$ <br> - every substance as a $\qquad$ <br> - High solubility: a $\qquad$ amount of solute can dissolve in solvent <br> - Low solubility: a $\qquad$ amount of solute can dissolve in solvent <br> - Insoluble: solute $\qquad$ in solvent at all. (Ex: $\qquad$ in water) <br> - the solubility of a solute can be $\qquad$ <br> - $\uparrow$ $\qquad$ $\qquad$ solubility of solids, $\qquad$ solubility of gases <br> - $\uparrow$ $\qquad$ $\qquad$ solubility of gases |
| Summary: <br> Classifying <br> Matter |  |
